# Propagation Features of Beams with Axially Symmetric Polarization 

A.V. Nesterov, V.G. Niziev<br>Institute on Laser \& Information Technologies of RAS<br>Shatura, Moscow region, 140700 RUSSIA

#### Abstract

The general solution of the wave equation for the axially symmetric polarized (ASP) beams consists of two independent solutions: azimuthally polarized beam and beam with longitudinal and radial field components. Maximum of the longitudinal field is at the beam axis where the transverse component equals to zero. In spite of the longitudinal component is maximum in the waist it doesn't contribute to beam divergence here, therefore the wave front of ASP-beams is flat in the focal plane. The ASP-beams are free from polarization aberrations, which are inherent for linearly polarized beams passing through a lens with large annular apertures, and these beams are prospective for experiments on obtaining "diffraction free" beams. The formulae and their analysis for electromagnetic field in the case of sharp focusing of ASP-beams in Debye approximation are presented.

## 1. Introduction

Beams with axially symmetric polarization (ASP) are of special interest as from the theoretical viewpoint and from the viewpoint of their applications. The full axial symmetry of these beams (including amplitude, phase and polarization) makes them optimum in many applications: light transmission by metallic waveguides, laser materials processing, experiments on inertial fusion and others [1-4]. An effective method for generating such beams by using a polarization selective intracavity mirror was demonstrated in paper [5]. According to this, the task of describing the properties of axially symmetric polarized beams such as propagation, diffraction and focusing becomes actual. The main feature of ASP-beams is that the angle between the electric vector at a point and the radius directed to this point is constant over the beam cross-section. Well known examples are radially and azimuthally polarized beams. The authors of paper [6] showed that the symmetry of the intensity distribution of ASP-beams is a direct consequence of their polarization symmetry.

Fig. 1. Schematic view of relative location of the electromagnetic field and the wave vector $\mathbf{k}$ for a beam with r-z directed field.

The usual scalar wave equation is derived from the vector wave equation in assumption of homogeneous polarization distribution over the beam cross-section. In this case one neglects a longitudinal component of the electric field naturally connected with the beam divergence in such approach. In the case of ASP-beams the maximum amplitude is on the axis where the transversal
J. Opt. B: Quantum and Semiclassical Optics 2001, v.2, n.2, p.215-219.
component $(\mathbf{E}$ or $\mathbf{H})$ of the field equals to zero. Therefore there is no reason to neglect the longitudinal field here.
The aim of the paper is analytical investigating features of propagation of ASP-beams for creating comparatively full and logical description of such beams in different appearances: paraxial propagation, sharp focusing, diffraction.

## 2. General approach to ASP-beams

The equation for "slowly varying amplitude of monochromatic axially symmetric polarized field (without multiplier $\exp (\mathrm{ikz})$ ) has the form

$$
\begin{gather*}
\left(\hat{\mathrm{L}}_{\mathrm{r}}+\hat{\mathrm{L}}_{\varphi}+\hat{\mathrm{L}}_{\mathrm{z}}\right) \mathbf{E}=0,  \tag{1}\\
\hat{\mathrm{~L}}_{\mathrm{r}}=\frac{1}{\mathrm{r}} \frac{\partial}{\partial \mathrm{r}} \mathrm{r} \frac{\partial}{\partial \mathrm{r}}, \quad \hat{\mathrm{~L}}_{\varphi}=\frac{1}{\mathrm{r}^{2}} \frac{\partial^{2}}{\partial \varphi^{2}}, \quad \hat{\mathrm{~L}}_{\mathrm{z}}=2 \mathrm{ik} \frac{\partial}{\partial \mathrm{z}}+\frac{\partial^{2}}{\partial \mathrm{z}^{2}}, \\
\mathbf{E}=\mathrm{E}_{\mathrm{r}} \cdot \mathbf{n}_{\mathrm{r}}+\mathrm{E}_{\varphi} \cdot \mathbf{n}_{\varphi}+\mathrm{E}_{\mathrm{z}} \cdot \mathbf{n}_{\mathrm{z}} .
\end{gather*}
$$

The field components $E_{r}, E_{\varphi}, E_{z}$ are independent on $\varphi$ and are functions of $r$ and $z$. Taking into account the expressions $\partial n_{r} / \partial \varphi=-n_{\varphi}, \partial n_{\varphi} / \partial \varphi=n_{r}$ (the other derivatives for the unit vectors equal to zero) we get from (1) the following equations for the field components

$$
\begin{align*}
& \left(\hat{\mathrm{L}}_{\mathrm{r}}-\frac{1}{\mathrm{r}^{2}}+\hat{\mathrm{L}}_{\mathrm{z}}\right) \mathrm{E}_{\mathrm{r}}=0  \tag{2a}\\
& \left(\hat{\mathrm{~L}}_{\mathrm{r}}-\frac{1}{\mathrm{r}^{2}}+\hat{\mathrm{L}}_{z}\right) \mathrm{E}_{\varphi}=0  \tag{2b}\\
& \left(\hat{\mathrm{~L}}_{\mathrm{r}}+\hat{\mathrm{L}}_{z}\right) \mathrm{E}_{\mathrm{z}}=0 \tag{2c}
\end{align*}
$$

Maxwell equation in the form

$$
\begin{equation*}
\frac{1}{\mathrm{r}} \frac{\partial\left(\mathrm{rE}_{\mathrm{r}}\right)}{\partial \mathrm{r}}+\frac{\partial \mathrm{E}_{\mathrm{z}}}{\partial \mathrm{z}}=0 \tag{3}
\end{equation*}
$$

has to add to the system (2). Thus, the general solution for an ASP-beam consists of two independent solutions for an azimuthally polarized beam (2b) and for a polarized beam with radial and longitudinal components of field:

$$
\mathbf{E}=\mathrm{k}_{1} \cdot \mathrm{E}_{\varphi} \cdot \mathbf{n}_{\varphi}+\mathrm{k}_{2} \cdot\left(\mathrm{E}_{\mathrm{r}} \cdot \mathbf{n}_{\mathrm{r}}+\mathrm{E}_{\mathrm{z}} \cdot \mathbf{n}_{\mathrm{z}}\right),
$$

J. Opt. B: Quantum and Semiclassical Optics 2001, v.3, n.2, p.215-219.
where $\mathrm{k}_{1}$ and $\mathrm{k}_{2}$ are arbitrary complex coefficients. Figure 1 illustrates a beam with r-z electric field components $\left(k_{1}=0\right)$. The beams with azimuthal, radial or intermediate direction of polarization are obtained by zero phase shift $\Delta \varphi$ between two solutions $(2,3)$ and different magnitudes of $k_{1}$ and $k_{2}$. If $\left|k_{1}\right|=\left|k_{2}\right|$ and $\Delta \varphi=\pi / 2$, the beam is circularly polarized and the phase of electrical vector equals to the azimuthal angle. It is helical mode [7] with circular polarization (Figure 2a). It is clear that this beam penetrating through the $\lambda / 4$ retarder becomes a classical linearly polarized mode. In the contrary to the helical mode with circular polarization the radially polarized beam with "normal" phase distribution over the cross section is shown on Figure 2b.
$\mathrm{H}_{\mathrm{r}} \mathrm{H}_{\mathrm{z}}$, arb. un.

Fig. 3. Radial distribution of longitudinal components $\mathrm{H}_{\mathrm{z}}$ (filled region) and radial $\mathrm{H}_{\mathrm{r}}$ (curve), obtained from (5).

The physical reason of existence of two independent solutions is that the azimuthally polarized beam retains its state of polarization but the ratio of longitudinal and transverse components of field changes.
The authors of [8] considered in details the famous paradox of classic paraxial approximation in the study of modes in spherical laser resonators. The solution for plane polarized mode has spherical wavefront. This zero order approximation contradicts to exact Maxwell equations. The first-order field is found to be a longitudinal field.
In the contrary to plane polarization in our case for ASP beams we can contend that:
a) The solutions with or without longitudinal component of field are separated each other.
b) It is true for common case without paraxial restriction.
c) Both solutions can be found by the same methods. We should start calculation from the azimuthally directed field E or H , and then calculate radial or longitudinal components of H or E respectively.

## 3. Self-similar solutions for ASP-beams in paraxial approximation

The self-similar solutions of the equation (2b) in paraxial approximation

$$
\begin{equation*}
\frac{1}{\mathrm{r}} \frac{\partial}{\partial \mathrm{r}} \mathrm{r} \frac{\partial \mathrm{E}_{\varphi}}{\partial \mathrm{r}}-\frac{1}{\mathrm{r}^{2}} \mathrm{E}_{\varphi}+2 \mathrm{ik} \frac{\partial \mathrm{E}_{\varphi}}{\partial \mathrm{z}}=0 \tag{4}
\end{equation*}
$$

are well known Laguerre-Gauss beams $\mathrm{TEM}_{\mathrm{p} 1 *}$. The components of electric and magnetic field of the beam $\mathrm{TEM}_{01 *}$ can be calculated:

$$
E_{\varphi}=\frac{2}{\sqrt{\pi}} \cdot \frac{1}{w} \cdot R \cdot \exp \left(-\mathrm{R}^{2}\right) \cdot \exp (i \theta)
$$

J. Opt. B: Quantum and Semiclassical Optics 2001, v.24, n.2, p.215-219.

$$
\begin{gather*}
\mathrm{H}_{\mathrm{r}}=\frac{\mathrm{i}}{\pi \sqrt{\pi}} \frac{\lambda}{\mathrm{w}} \frac{1}{\mathrm{z}_{0}} \mathrm{R} \cdot(\mathrm{~m}+\mathrm{in}) \cdot \exp \left(-\mathrm{R}^{2}\right) \cdot \exp (\mathrm{i} \theta),  \tag{5}\\
\mathrm{H}_{\mathrm{z}}=-2 \frac{\mathrm{i}}{\pi \sqrt{\pi}} \cdot \frac{\lambda}{\mathrm{w}} \frac{1}{\mathrm{w}} \cdot\left(1-\mathrm{R}^{2}-\mathrm{iZR} \mathrm{R}^{2}\right) \cdot \exp \left(-\mathrm{R}^{2}\right) \cdot \exp (\mathrm{i} \theta),
\end{gather*}
$$

where $\mathrm{R}=\mathrm{r} / \mathrm{w}, \mathrm{w}^{2}=\mathrm{w}_{0}^{2} \cdot\left(1+\mathrm{Z}^{2}\right), \mathrm{Z}=\mathrm{z} / \mathrm{z}_{0}, \mathrm{Z}_{0}=\frac{\pi \mathrm{w}_{0}^{2}}{\lambda}, \mathrm{w}_{\mathrm{o}}$ is the beam radius in the waist, $\lambda$ is the wavelength;

$$
\theta=2 \operatorname{arctg} \mathrm{Z}-2 \mathrm{Z} \frac{\mathrm{z}_{0}^{2}}{\mathrm{w}_{0}^{2}}-\mathrm{ZR}^{2} ; \quad \mathrm{m}=2 \mathrm{Z} \frac{\mathrm{w}_{0}^{2}}{\mathrm{w}^{2}}\left(\mathrm{R}^{2}-1\right) ; \quad \mathrm{n}=\frac{2 \mathrm{w}_{0}^{2}}{\mathrm{w}^{2}}-2 \frac{\mathrm{z}_{0}^{2}}{\mathrm{w}_{0}^{2}}+\mathrm{R}^{2} \frac{\mathrm{Z}^{2}-1}{\mathrm{Z}^{2}+1}
$$

One can calculate the amplitude of magnetic vector and its direction. Note that $\mathrm{H}_{\mathrm{z}}$ has the phase shift $\pi / 2$ relative to $\mathrm{E}_{\varphi}$ in cross-section $\mathrm{Z}=0$. Therefore the time averaged wave vector has no radial component over this cross-section and the wave front is flat. Figure 3 shows the vector $\mathbf{H}$ distribution in the waist. Maximum values of magnetic vector $\mathrm{H}_{\mathrm{z}}$ and $\mathrm{H}_{\mathrm{r}}$ is achieved at $\mathrm{R}_{0}=0$ and $\mathrm{R}_{0}=1 / \sqrt{2}$ respectively. Their ratio is of order of $\lambda / \mathrm{w}_{0}$ :

$$
\begin{equation*}
\frac{\left(\mathrm{H}_{\mathrm{z}}\right)_{\max }}{\left(\mathrm{H}_{\mathrm{r}}\right)_{\max }}=\frac{\left(\mathrm{H}_{\mathrm{z}}\right)_{\mathrm{R}_{0}=0}}{\left(\mathrm{H}_{\mathrm{r}}\right)_{\mathrm{R}_{0}=1 / \sqrt{2}}} \sim \frac{\lambda}{\mathrm{w}_{0}} \tag{6}
\end{equation*}
$$

It is evident that these results are valid by mutual substitute of $\mathbf{E}$ and $\mathbf{H}$. The self-similar solutions (4) can be also resonator modes.

## 4. Huygens-Fresnel integral for ASP-beams

We consider the ASP-beams with axially symmetric intensity distribution. The solution of equation (4) in general case is obtained by the method of separation of variables and can be expressed by the integral:

$$
\begin{equation*}
\mathrm{E}_{\varphi}(\mathrm{r}, \mathrm{z})=\int_{0}^{\infty} \mathrm{A}\left(\sigma^{2}\right) \cdot \mathrm{J}_{1}(\sigma r) \cdot \exp \left(-\frac{\mathrm{i}}{2 \mathrm{k}} \sigma^{2} \mathrm{z}\right) \cdot \mathrm{d} \sigma^{2} \tag{7}
\end{equation*}
$$

Here $\sigma^{2}$ is the constant of separation.
We consider $\delta$-ring source at $\mathrm{z}=0$ :

$$
\delta\left(\mathrm{r}-\mathrm{r}_{0}\right)=\int_{0}^{\infty} \mathrm{A}\left(\sigma^{2}\right) \cdot \mathrm{J}_{1}(\sigma \mathrm{r}) \cdot \mathrm{d} \sigma^{2}
$$

Using the known formula

$$
\delta\left(\mathrm{r}-\mathrm{r}_{0}\right)=\mathrm{r}_{0} \int_{0}^{\infty} \mathrm{J}_{1}(\mathrm{vr}) \cdot \mathrm{J}_{1}\left(\mathrm{vr}_{0}\right) \cdot \mathrm{v} \cdot \mathrm{dv}
$$

we find $\mathrm{A}\left(\sigma^{2}\right)$ and obtain from (7) the expression

$$
\mathrm{G}_{\varphi}\left(\mathrm{r}_{0}, \mathrm{r}, \mathrm{z}\right)=\frac{\mathrm{r}_{0}}{2} \int_{0}^{\infty} \mathrm{J}_{1}\left(\sigma \mathrm{r}_{0}\right) \cdot \mathrm{J}_{1}(\sigma r) \cdot \exp \left(-\frac{\mathrm{i}}{2 \mathrm{k}} \sigma^{2} \mathrm{z}\right) \cdot \mathrm{d} \sigma^{2}
$$

After integrating according to

$$
\int_{0}^{\infty} \exp (-i a x) \cdot J_{1}(2 \gamma \sqrt{x}) \cdot J_{1}(2 \delta \sqrt{x}) \cdot d x=\frac{1}{\text { ia }} \cdot J_{1}\left(\frac{2 \gamma \delta}{a}\right) \cdot \exp \left(-\frac{\gamma^{2}+\delta^{2}}{\text { ia }}\right)
$$

the Green function acquires the form:

$$
\begin{equation*}
\mathrm{G}_{\varphi}\left(\mathrm{r}_{0}, \mathrm{r}, \mathrm{z}\right)=\frac{\mathrm{kr}_{0}}{\mathrm{iz}} \mathrm{~J}_{1}\left(\frac{\mathrm{krr}_{0}}{\mathrm{z}}\right) \cdot \exp \left(\mathrm{ik}\left(\mathrm{z}+\frac{\mathrm{r}^{2}+\mathrm{r}_{0}^{2}}{2 \mathrm{z}}\right)\right) \tag{8}
\end{equation*}
$$

J. Opt. B: Quantum and Semiclassical Optics 2001, v.J, n.2, p.215-219.

Equation (1) describes the slow amplitude without the factor $\exp (\mathrm{ikz})$, as introduced in (8). Thus, the distribution of azimuthally polarized beam in paraxial approximation is given by the integral

$$
\begin{equation*}
\mathrm{E}_{\varphi}\left(\mathrm{r}^{\prime}, \mathrm{z}^{\prime}\right)=\int_{0}^{\infty} \mathrm{E}_{\varphi}^{0}\left(\mathrm{r}_{0}\right) \cdot \mathrm{G}_{\varphi}\left(\mathrm{r}_{0}, \mathrm{r}^{\prime}, \mathrm{z}^{\prime}\right) \cdot \mathrm{dr}_{0} \tag{9}
\end{equation*}
$$

Another more complicated method of obtaining expression (8) based on vector superposition of two scalar solutions of wave equations for two transverse coordinates, was used in paper [9].
In the case of $r$ - $z$ directed field the electric vector in cross-section $\mathrm{z}=0$ is given by:

$$
\mathbf{E}^{0}\left(\mathrm{r}_{0}, \mathrm{z}=0\right)=\mathrm{E}_{\mathrm{r}}^{0}\left(\mathrm{r}_{0}, \mathrm{z}=0\right) \cdot \mathbf{n}_{\mathrm{r}}+\mathrm{E}_{\mathrm{z}}^{0}\left(\mathrm{r}_{0}, \mathrm{z}=0\right) \cdot \mathbf{n}_{\mathrm{z}} .
$$

Calculating the magnetic component from

$$
\mathrm{H}_{\varphi}^{0}(\mathrm{r}, \mathrm{z}=0)=-\frac{\mathrm{i}}{\mathrm{k}} \cdot\left(\frac{\partial \mathrm{E}_{\mathrm{r}}^{0}}{\partial \mathrm{z}}-\frac{\partial \mathrm{E}_{\mathrm{z}}^{0}}{\partial \mathrm{r}}\right)
$$

and applying formulae (8) and (9) for azimuthally directed field we obtain the solution for the vector $\mathbf{H}$ and therefore for $\mathbf{E}$.

## 5. Fraunhofer diffraction on a ring slit

One can solve the task of Fraunhofer diffraction of azimuthally polarized beams on a ring slit on the base of the Green function (8). By analogy with [10], the intensity distribution in the far field expressed by vectorial angle $\theta$ is given by

$$
\begin{equation*}
\frac{\mathrm{dI}}{\mathrm{I}_{0}}=\frac{\mathrm{k}^{2} \cdot \mathrm{R} \cdot \Delta \mathrm{R}}{2 \cdot \pi} \cdot \mathrm{~J}_{1}^{2}(\mathrm{kR} \theta) \cdot \mathrm{d} \Omega \tag{10}
\end{equation*}
$$

Here $R$ and $\Delta R$ are the radius and the width of the radiating ring in the cross section $z=0, d \Omega$ is the element of solid angle.
For comparison, the formula for diffraction of a linearly polarized beam on a ring slit in the same notation has the form

$$
\begin{equation*}
\frac{\mathrm{dI}}{\mathrm{I}_{0}}=\frac{\mathrm{k}^{2} \cdot \mathrm{R} \cdot \Delta \mathrm{R}}{2 \cdot \pi} \cdot \mathrm{~J}_{0}^{2}(\mathrm{kR} \theta) \cdot \mathrm{d} \Omega \tag{11}
\end{equation*}
$$

The "diffraction free" beams were reported to be obtained experimentally [11]. A linearly polarized beam passed the ring slit and then the lens positioned at the focal distance from the slit in that experiment. After passing the lens the beam acquired a Bessel field distribution, cut by lens aperture. Degree of approximation to the ideal Bessel function in this case is dependent on lens aperture. But the larger are lens aperture, the larger are polarization aberrations. Using ASP-beams in this scheme one can remove this disadvantage and provide "diffraction free" beam with intensity distribution in the form of first order Bessel function.
As for the same diffraction of the beam with r-z direction of field, the intensity distribution of the radial component has also the form (10) and the longitudinal component is described by the expression (11) with the additional factor $1 /(\mathrm{k} \cdot \mathrm{R})^{2}$.

## 6. Debye approximation for sharp focusing of ASP-beams

The task of sharp focusing is outside the above discussed paraxial approximation. It is usually solved with the Debye method. According to this method, the field distribution in the focal region is formed by wave rays, converging inside the cone restricted by the aperture of the optical system. The phase of the wave ray is described by multiplier $\exp (\mathbf{i k r})$,

$$
\begin{aligned}
& \mathbf{k}=(-k \cdot \sin \theta \cdot \cos \beta,-k \cdot \sin \theta \cdot \sin \beta,-k \cdot \cos \alpha), \\
& \mathbf{r}=(r \cdot \sin \theta \cdot \cos \varphi, r \cdot \sin \theta \cdot \sin \varphi, r \cdot \cos \theta) .
\end{aligned}
$$

J. Opt. B: Quantum and Semiclassical Optics 2001, v.ъ6, n.2, p.215-219.
where $\mathbf{k}$ is the ray vector and $\mathbf{r}$ is radius-vector in coordinate system connected to the focus. The polarization direction is perpendicular to $\mathbf{k}$ and is determined relative to the angle between $\mathbf{k}$ and the optical lens axis.

Fig. 4. The ratio of maximum amplitudes of longitudinal and transverse electrical fields in the focal plane versus the focal length in Debye approximation.

According to [12,13], there is the following expression for the electric vector in the general case:

$$
\mathbf{E}=\frac{-\mathrm{ik}}{2 \pi} \int_{0}^{2 \pi \theta_{1}} \int_{0} \mathrm{~A}(\alpha) \cdot \mathbf{p}(\alpha, \beta) \cdot \exp (\mathrm{ikr}) \cdot \sin \alpha \cdot \mathrm{d} \alpha \mathrm{~d} \beta
$$

Here $\theta_{1}$ is the angle of semiaperture of the optical system, $\mathbf{p}(\alpha, \beta)$ is the unit vector which coincides with the direction of $\mathbf{E}$ in the region extending from the lens to the focal plane, $\mathrm{A}(\alpha)$ is the coefficient connected with the beam distribution $A_{0}(\rho)$ incident upon the focusing system and its focal length f . $\mathrm{A}(\alpha)=\mathrm{A}_{0}(\mathrm{f} \sin \alpha) \cdot \sqrt{\cos \alpha}$ for aplanatic system.

The unit vector $\mathbf{p}(\alpha, \square \beta)$ in the case of ASP-beams can be expressed in the form $\mathrm{e}^{\mathrm{i} \beta}$ for azimuthal and $\mathrm{e}^{\mathrm{i}(\beta+\pi / 2)}$ for $\mathrm{r}-\mathrm{z}$ types of polarization. Taking into account this representation, the expressions for vector $\mathbf{E}$ in the focal region are given by:

$$
\begin{gathered}
\mathrm{E}_{\mathrm{r}}=0, \quad \mathrm{E}_{\mathrm{z}}=0 \\
\mathrm{E}_{\varphi}(\mathrm{u}, \mathrm{v})=\mathrm{k} \int_{0}^{\theta_{1}} \mathrm{~A}(\alpha) \cdot \mathrm{J}_{1}\left(\mathrm{v} \cdot \sin \alpha / \sin \theta_{1}\right) \cdot \exp \left(\mathrm{i} \cdot \mathrm{u} \cdot \cos \alpha / \sin ^{2} \theta_{1}\right) \sin \alpha \mathrm{d} \alpha \mathrm{~d} \beta
\end{gathered}
$$

for azimuthal polarization, and

$$
\begin{gathered}
E_{r}(u, v)=\frac{k}{2} \int_{0}^{\theta_{1}} A(\alpha) \cdot J_{1}\left(v \cdot \sin \alpha / \sin \theta_{1}\right) \cdot \exp \left(i \cdot u \cdot \cos \alpha / \sin ^{2} \theta_{1}\right) \sin 2 \alpha d \alpha d \beta \\
E_{z}(u, v)=-i \cdot k \int_{0}^{\theta_{1}} A(\alpha) \cdot J_{0}\left(v \cdot \sin \alpha / \sin \theta_{1}\right) \cdot \exp \left(i \cdot u \cdot \cos \alpha / \sin ^{2} \theta_{1}\right) \sin ^{2} \alpha d \alpha d \beta \\
E_{\varphi}=0
\end{gathered}
$$

J. Opt. B: Quantum and Semiclassical Optics 2001, v.3, n.2, p.215-219.
for radial polarization, where v and u are the optical coordinates:

$$
\mathrm{v}=\mathrm{k} \cdot \mathrm{r} \cdot \sin \theta \cdot \sin \theta_{1}=\mathrm{k} \cdot \rho \cdot \sin \theta_{1}, \quad \mathrm{u}=\mathrm{k} \cdot \mathrm{r} \cdot \cos \theta \cdot \sin ^{2} \theta_{1}=\mathrm{k} \cdot \mathrm{z} \cdot \sigma \mathrm{v}^{2} \theta_{1}
$$

We used for derivation of these expressions the integral:

$$
\int_{0}^{2 \pi} \exp [\mathrm{i} \cdot \mathrm{n} \cdot \beta+\mathrm{i} \cdot \mathrm{t} \cdot \cos (\beta-\gamma)] \cdot \mathrm{d} \beta=2 \pi \cdot \mathrm{i}^{\mathrm{n}} \cdot \mathrm{~J}_{\mathrm{n}}(\mathrm{t}) \exp (\mathrm{i} \cdot \mathrm{n} \cdot \gamma)
$$

The field with electric vector parallel to the optical lens axis with maximum on this axis appears in the case of radially polarized beam.

Figure 4 illustrates the ratio of maximum amplitudes of longitudinal and transverse electrical fields in the focal plane versus the focal length in Debye approximation. The part of the longitudinal components decreases at increasing of focal length. The longitudinal component possesses the larger divergence in comparison with the transverse component (Figure 5).

$$
\mathrm{E}_{\mathrm{z}}, \mathrm{E}_{\mathrm{r}}, \text { arb. un. }
$$

Fig. 5. The illustration of relative distribution of $E_{z}$ (filled regions) and $E_{r}$ (curves) at the waist $z=0$ (thick lines) and at the distance $\mathrm{z}=8 \mathrm{w}_{0}$ (thin lines). The focal distance is $\mathrm{f}=2.6 \mathrm{w}_{0}$. The scale of all curves is the same.

## 7. Green function for non-paraxial ASP-beams.

The vector wave equation (1) is transformed to the scalar equation for the azimuthally polarized beam:

$$
\frac{1}{\mathrm{r}} \frac{\partial}{\partial \mathrm{r}} \mathrm{r} \frac{\partial \mathrm{u}_{\varphi}}{\partial \mathrm{r}}-\frac{1}{\mathrm{r}^{2}} \mathrm{u}_{\varphi}+\frac{\partial^{2} \mathrm{u}_{\varphi}}{\partial \mathrm{z}^{2}}+2 \mathrm{ik} \frac{\partial \mathrm{u}_{\varphi}}{\partial \mathrm{z}}=0
$$

The Green function of this equation can be calculated the following way:

$$
\mathrm{G}\left(\mathrm{r}_{0}, \mathrm{r}, \mathrm{z}\right)=\frac{\mathrm{r}_{0}}{2} \int_{0}^{\infty} \mathrm{J}_{1}\left(\sigma \mathrm{r}_{0}\right) \cdot \mathrm{J}_{1}(\sigma r) \cdot \exp \left[\left(-\mathrm{ik} \pm \sqrt{\sigma^{2}-\mathrm{k}^{2}}\right) \cdot \mathrm{z}\right] \cdot \mathrm{d} \sigma^{2}
$$

This formula for non-paraxial beams is a generalisation of the expression (8).

## 8. Conclusion

The general solution for the ASP-beams consists of two independent solutions: an azimuthally polarized beam and a beam with longitudinal and radial components of field. Maximum of the longitudinal field is on the beam axis where the transverse component equals to zero. The ratio of maximum amplitudes of longitudinal and transverse components is of order of
J. Opt. B: Quantum and Semiclassical Optics 2001, v.8, n.2, p.215-219.
$\lambda / \mathrm{w}_{0}$ ( $\lambda$ is the wavelength, $\mathrm{w}_{0}$ is waist radius). The longitudinal component does not contribute to beam divergence in the waist, therefore the wave front of ASP-beams is flat in the focal plane.

Fraunhofer diffraction of ASP-beams on a ring slit gives a field distribution proportional to the first order Bessel function. The ASP-beams are free from polarization aberrations, which are inherent for linearly polarized beams passing through a lens with large annual aperture, and are prospective for experiments on obtaining "diffraction free" beams.

The formulae and their analysis for electromagnetic field in the case of sharp focusing of ASP-beams are presented.
